CHECK POINT RESEARCH

Cyber Attack Trends

2018 MID-YEAR REPORT

101010-00

Check Point Cyber Attack Trends: Mid-Year Report 2018

Introduction

When it comes to the global cyber landscape, threats are ever evolving, keeping organizations, as well as the security community, constantly challenged. From taking advantage of the Blockchain trading systems to developing new attack methods in the thriving mobile arena, as well as adapting previous attack tools to the cloud environment, there are clear uses of current technological developments and their rising implementation in the 2018 cyber threat landscape.

So far this year, the different strains of malware and their authors have proven to be capable of much more than previously imagined, with more sophistication and with a new level of agility. As seen in our analysis of the <u>GandCrab</u> Ransomware, malware are now rapidly adapting in real-time to security solutions offered by security vendors.

One of the biggest ongoing trends is Cryptominers and crypto-related threats as a whole. Indeed, cryptominers have taken the world by storm, becoming the leading attack vector used by threat actors this year, overtaking even Ransomware. So far, Cryptominers have greatly improved their capabilities as well as upgraded their targets array: <u>servers</u>, <u>mobile devices</u>, <u>industrial systems</u> and <u>cloud infrastructure</u> – no one is left behind.

The first half of 2018 has also featured some new and interesting trends. The Cloud infrastructure for instance, has become one of the most attractive targets for threat actors; as the vast amount of sensitive data along with the available computing resources reside on the cloud environment, have easily captivated the attackers' attention. <u>Tesla's cloud servers</u> infected with Monero miner earlier this year and a massive <u>leak</u> of sensitive data of FedEx customers are just two examples of what 2018 has brought to us.

To provide organizations with the best level of protection, security experts must be attuned to the ever-changing landscape and the latest threats and attack methods. The Check Point Global Threat Intelligence Trends report provides a comprehensive overview of the malware landscape in the top categories of Cryptominers, Ransomware, banking and mobile threats, based on threat intelligence data drawn from the <u>ThreatCloud World Cyber Threat Map</u> between January and June 2018.

Global Trends

The Evolution of Cryptominers

It's difficult not to notice the incredible surge in Cryptomining attacks. During the first half of 2018, Cryptominers dominate the top <u>cyber-attacks</u> and malware families seen in the wild. Overtaking Ransomware, Cryptominers <u>affected</u> over 42% of organizations worldwide, compared to 20.5% at the end of 2017. Over the past six months, Cryptomining attacks are estimated to have 'earned' their users more than \$2.5 billion, and still counting.

Since their creation, Cryptominers have come a long way. Evolving from simple website compromise, Cryptominers have been observed this year spreading through <u>Facebook Messenger</u>, <u>YouTube ads</u> and <u>Google Play</u>, while infecting <u>tens of thousands of websites</u>, <u>personal computers</u> and powerful severs such as <u>Jenkins</u>. In 2018, Cryptominers have upgraded and vastly improved their abilities, becoming more sophisticated and even <u>destructive</u>.

Motivated by a clear interest to increase the percentage of computational resources leveraged, and crafted to be even more profitable, Cryptominers today target anything that could be perceived as being in their way. As a result, we have witnessed Cryptominers targeting <u>SQL Databases</u>, <u>industrial systems</u>, a Russian <u>nuclear plant</u>, and even <u>cloud</u> infrastructure. Cryptominers have also highly evolved recently to exploit high profile <u>vulnerabilities</u> and to <u>evade</u> sandboxes and security products in order to expand their infection rates.

The mobile arena was not deprived of Cryptomining attacks either. Last April, Android Cryptominer dubbed <u>HiddenMiner</u> targeted numerous devices, continuously mining Monero until the devices' resources were drained. Mobile miners have even managed to <u>breach Apple's garden wall</u> and penetrated the App Store, with a malware trying to steal victims' login credentials to cryptocurrency wallets.

Adding more fuel to the fire, since the beginning of 2018 a variety of new attack methods have surfaced, leveraging the potential that lays in cryptocurrency trading systems. Among others, these methods include virtual wallet and credential theft, cryptocurrency transaction maneuvering, as well as <u>ICO scams</u> (Initial Coin Offering) that lure victims to invest in a fake premature cryptocurrency.

Moreover, other malware families have begun integrating mining capabilities into their arsenal; <u>Ransomware</u>, as well as prominent Banking Trojans including <u>Panda</u> and <u>TrickBot</u>, are now targeting not only bank accounts but also cryptocurrency wallets and trading system accounts, adding features of cryptocurrency credential theft to their arsenal.

As threat actors become more aware of the lucrativeness of the crypto-business, even more than other exploits, there is almost never a day that goes by without some kind of crypto-threat making the headlines.

New Threats from Transition to the Cloud

The cloud environment has changed the way companies manage, store and share their data, applications, and workloads. Along a wide range of benefits, the cloud infrastructure also introduces a new, fertile and attractive environment for attackers who crave for the enormous amount of available computing resources and sensitive data it holds.

Indeed, 2018 has brought us various sophisticated techniques and tools exploited against cloud storage services. In the past year alone, 51% of organizations worldwide have <u>experienced</u> cloud-based attacks, including <u>FedEx</u>, Intel, and <u>Honda</u>.

Several cloud-based attacks, mainly those involving data exfiltration and information disclosure, derived from poor security practices. Credentials left available on public source code <u>repositories</u> or the use of weak passwords are just some examples of how threat actors gained access and control over unprotected resources hosted in the cloud.

Another rising threat taking the cloud environment by storm is the infamous Cryptominers, targeting the cloud infrastructure in order to exploit the vast computational power it presents, and generate huge profits for threat actors. In the first half of 2018, we have witnessed cryptominers targeting two of the cloud's core components - Docker and Kubernetes systems. This is how, for example, <u>Tesla's internal cloud</u> servers were infected with a Monero Cryptominer a few months ago.

Application Programming Interfaces (APIs) that are used to manage, interact and extract information from services have also been a target for threat actors. The fact that cloud API's are accessible via the Internet has opened a window for threat actors to take advantage and gain considerable access to cloud applications.

As time passes, it seems that the cloud's threats will continue to evolve; attackers will continue to develop more and more tools for their cloud playground, pushing the limits of the public cloud services. Indeed, as new cloud exploitations emerge, there is no doubt that the next attack is already taking place.

Multi-Platform Attacks: Desktop and Mobile

In the beginning of 2018, a new Advanced Persistent Threat (APT) dubbed 'Dark Caracal' was revealed, possibly after five years of under the radar activity. Though APT groups have carried out

extensive espionage campaigns in the past few years, this group presents a unique method of operation which marks one of 2018's most prominent trends. It began collecting sensitive data from mobile devices but has recently shifted to a more effective technique of using one piece of malware which infects Windows, Linux and Mac OS. Whether they are based on one malware or not, multi-platform attacks may have a crippling on its victims, whether they be private homes in which all desktop machines, mobile devices and consumer devices are attacked at once, or an enterprise whose industrial systems and data centers get attacked simultaneously.

Up until the end of 2017, multi-platform malware was witnessed in only a handful of occasions, but as predicted, the rise in the number of consumer connected devices and the growing market share of operating systems which are not Windows has led to an increase in cross-platform malware. Campaign operators implement various techniques in order to take control over the campaigns' different infected platforms.

In the first half of 2018, we witnessed the Android Banking Trojan "<u>Roaming Mantis</u>" roaming further afield than it ever had before, targeting both iOS users and personal computers' resources for mining operations, allowing its authors to vastly accelerate their infection rate.

With the introduction of new technologies like powerful smartphones and Office 365, potential victims are no longer using single endpoints but rather several fully connected devices and services.

This introduces a whole new environment in which victims are exposed to more attack vectors that could be exploited by threat actors trying to find the weakest link that leads to a person or organization's data.

Mobile Malware throughout the Supply Chain

Getting infected with malware on a mobile device is by now nothing new. From being downloaded from a malicious URL or disguised as an innocent looking mobile app, there are various ways a device can be hacked.

In the first half of this year, however, we have witnessed an interesting trend – preinstalled malware. In several incidences malware was not pulled from an app store or downloaded from a malicious URL, but instead arrived already installed within the device. This March, Check Point researchers <u>revealed</u> a widespread mobile botnet dubbed 'RottenSys', infecting nearly five million Android devices. RottenSys, disguised as a legitimate 'System Wi-Fi service' app came preinstalled on millions of brand new smartphones manufactured by leading brands including Huawei, Xiaomi, Vivo and Samsung. In another case, 42 models of low-cost smartphones were found being sold with the Triada Banking Trojan <u>preinstalled</u>. Threat actors' ability to infiltrate somewhere along the supply chain is concerning and will continue to trouble us in the future.

In addition, with the growing dependence on our mobile devices, application markets are flooded with different apps designed to optimize a device's battery performance, allowing the users few more moments of joy with their smartphones. This year, it appears that threat actors have spotted the potential opportunities in this market, as we discovered a vast amount of these allegedly innocent apps were actually malware under disguise. Among them, Banking Trojans, Adware, and even sophisticated RATs such as <u>AndroRAT</u> masqueraded as a utility app named "TrashCleaner" and capable of stealing mobile network information, storage capacity, calendar events and preforming shell command executions.

Knowing that all of our personal and business life is being managed over some extremely hackable devices, these two phenomena of preinstalled malware and the constant rise of malicious mobile apps reflect how motivated threat actors are to exploit this arena.

Top Malicious File Types – H1 2018

File Type Activity Rate Over Time- H1 2018

Global Malware Statistics

Data comparisons presented in the following sections of this report are based on data drawn from the <u>Check Point ThreatCloud Cyber Threat Map</u> between January and June 2018.

Top Malware Families

Global

Figure 1: Most Prevalent Malware Globally: Percentage of corporate networks experiencing each malware type

For each of the regions below we present two graphs. The first details the most prevalent malware in that region followed by a second graph that details the malware families with the highest presence in that region compared to others.

Americas

Figure 7: Top Targeted Malware in the APAC

Global Analysis of Top Malware

CoinHive, the popular web-based Monero Cryptocurrency miner has maintained its place at the summit of the global and regional rank, with 25% of the organizations worldwide hit by it. Together with Cryptoloot and Jesscoin, the cryptominers squad has shown no signs of slowing its dominance, impacting an entire about 40% of the globe. Ever since CoinHive first released its JavaScript mining code last September, it is being integrated in tens of thousands of websites <u>at any given moment</u>, utilizing visitors' computing resources, and functioning as a lucrative replacement for online advertisements leveraged by threat actors. This year Coinhive was delivered intensively, being found hidden inside YouTube advertisements, distributed via Google's DoubleClick platform and Facebook Messenger, and also embedded in thousands of websites.

RIG exploit kit, one of the most prominent exploit kits in the wild with several different campaigns currently in action, has climbed its way up to the global and regional ranks. The RIG infection chain starts with a redirection to a landing page that contains JavaScript that checks for vulnerable plugins and exploits the browser. Rig delivers Exploits for Flash, Java, Silverlight and Internet Explorer, and was the first one to include the new Zero day vulnerability discovered this year in IE, tracked as CVE-2018-8174. In the first half of 2018 RIG has hit the headlines, pushing various payloads including Bunitu, cryptominers, and the popular SmokeLoader.

Top Cryptomining Malware

In this section the graphs illustrate the percentage of organizations that were affected by each Cryptomining malware. The graphs provide global views and also regional insights into the top Cryptomining malware.

EMEA

APAC

Cryptominers Global Analysis

First seen in the wild in May 2017, the open-source CPU mining software **XMRig** is ranked third in all of the regions. Being the most popular and exclusive mining code leveraged by threat actors, during the first half of 2018, the XMRig mining code has been utilized by wide range of cryptostrains - one of which is **RubyMiner**. Exclusively detected by Check Point researches on last January, Rubyminer got into the ranking list of global and regional ranks. Targeting unpatched Windows and Linux servers, rather than being injected into websites as most of the others in the rank, RubyMiner has attempted to exploit 30% of all corporate networks worldwide in order to mobilize poweful servers into its operator's mining pool.

Top Ransomware

Graphs in this section, the graphs represent the percentage of organizations that were affected by each Ransomware. The graphs present a global view and also regional insights into the top types of Ransomware.

Americas

Figure 13: Most Prevalent Ransomware in the Americas

EMEA

Figure 14: Most Prevalent Ransomware in EMEA

Figure 15: Most Prevalent Ransomware in APAC

Ransomware Global analysis

Locky Ransomware, which first emerged in February 2016, has kept the crown, leading the top global and regional ranks as one of the most prevalent Ransomware of 2018. Surprisingly, also the infamous **WannaCry** has maintained its high rank of 2017, although it has been a bit more than a year since it had spread like wildfire to hundreds of thousands of devices. It appears that even a year later there are still machines infected with WannaCry that keep scanning the internet for vulnerable Windows machines.

APAC

Top Banking Malware

In this section of the report the graphs illustrate the percentage of organizations that were affected by each banking malware. The graphs provide global views and also regional insights into the top banking malware

Global

Figure 16: The Most Prevalent Banking Malware Globally

Americas

Figure 17: Most Prevalent Banking Malware in the Americas

Figure 18: Most Prevalent Banking Malware in EMEA

Figure 19: Most Prevalent Banking Malware in APAC

Banking Malware Global Analysis

The most prominent banking Trojans, dominating the Global Top Banking Malware list, **Ramnit** and **Zeus**, have kept their place at the top of the list since the second half of 2017. Both are persistent and evolving banking Trojans capable of recognizing when a victim is visiting a banking website, and then utilize keylogging or web injects to harvest login credentials or more sensitive information such as PIN numbers. In addition **Dorkbot**, known malware that dates back to 2012, has entered back the top ranks, starring in the APAC top Banking malware and also ranked second in the Americans, in the EMEA and globally. Dorkbot, designed to allow its operators remote code execution capabilities alongside with a primary motivation to steal sensitive banking information, has been observed on last April using newly code injection technique dubbed "<u>Early bird</u>", allowing it to avoid detection by anti-malware security products.

Top Mobile Malware

In this section the graphs illustrate the percentage of organizations that were affected by each mobile malware. The graphs provide global views and also regional insights into the top mobile malware.

Global

Figure 20: Top Mobile Malware Globally

Americas

Figure 21: Top Mobile Malware in the Americas

EMEA

Figure 22: Top Mobile Malware in EMEA

Figure 23: Top Mobile Malware in APAC

Mobile Malware Global Analysis

Triada, a very powerful Android banking Trojan discovered in 2016 and considered to be one of the most advanced mobile threats, has reached the top of the global and regions rankings. Last March Triada was found pre-installed on 42 models of low-cost smartphones, infecting hundreds of thousands of victims and stealing their credit card data. Furthermore, a new Mobile malware family has entered the charts – **TheTruthSpy**, capable of monitoring WhatsApp messages, Facebook chats, and internet browsing history. TheTruthSpy only emerged in May 2018 and is already ranked third in the world, and second in EMEA and APAC.

APAC

Cyber Attack Categories by Region

Global Threat Index Map

Check Point's Threat Index is based on the probability that a machine in a certain country will be attacked by malware. This is derived from the ThreatCloud World Cyber Threat Map, which tracks how and where cyberattacks are taking place worldwide in real time.

Major Cyber Breaches (H1, 2018)

So far in 2018 cyber breaches continue to affect businesses in all sectors, putting at risk the sensitive information of billions of people. Moreover, threat actors are targeting all geographies as all regions suffered numerous attacks. Below is a recap of the major attacks in each region.

Americas

- **February:** Voter registration <u>information</u> of over 19.5 million California residents was leaked online via an unsecured MongoDB database and held for ransom by threat actors. The Sacramento Bee, a local Sacramento-area newspaper that announced itself to the source of the breach, refused to pay the ransom and deleted the database.
- **March**: The leading fitness company "Under Armour" <u>suffered</u> a major breach of the company's app, MyFitnessPal. The company announced that the breach had exposed the data of 150 million users of the app including their user names, email addresses and hashed passwords.
- **March**: Orbitz, an Expedia-owned travel site announced a <u>data breach</u> leading to the disclosure of 880,000 payment cards used for online purchasing, along with other personal information belonging to customers. The incident had taken place between October 2016 and December 2017.
- **April**: Hudson's Bay, the parent company of Saks Fifth Avenue and Lord & Taylor, <u>suffered</u> a major breach of the company's payment systems. The breach was attribute to the FIN7 APT group who managed to steal credit and debit card information of about five million consumers who had shopped at both of the retailers.
- May: The data-mining company, Cambridge Analytica, was been accused of exploiting <u>Facebook</u> to harvest up to 87 million individuals' personal details in order to target US voters in the <u>2016 Presidential election</u>. This successful exploitation was achieved by using an app that paid users to take a personality test and give consent for data collection.

Europe, the Middle East and Africa (EMEA)

- January: Norway's biggest health authority, Health South East RHF', suffered a data <u>breach</u>, which affected more than half of the nation's population. Cybercriminals stole the personal info and health records of around 2.9 million Norwegians.
- **February:** The <u>German Government</u> announced that it experienced a massive cyberattack in which several of its networks, including an isolated one, were breached and infected with malware for about a year. The breach was only discovered in December, and included the servers of the Interior Ministry and other unspecified ones. German authorities suspect the Russian hacking group APT28 was behind the attack.

- March: A serious security breach in an app named "Remini" left millions of <u>pictures</u> of Israeli children, as well as the personal details of more than 100,000 parents, vulnerable to being leaked to the internet. The app allows preschool teachers to contact the parents and share any relevant information including schedules of classroom activities, pictures videos and personal information with them.
- **April**: The New Business Center in Helsinki, Finland, <u>fell victim</u> to a major data breach. Threat actors stole over 130,000 users' login usernames and passwords which were stored on the site in plain-text.
- **May:** A <u>database</u> containing the sensitive personal data of nearly one million South Africans were publicly leaked online. The database was discovered on a public web server belonging to a company that handles electronic traffic fine payments in South Africa and included names, ID numbers, e-mail addresses, and passwords.

Asia-Pacific (APAC)

- January: <u>Aadhaar</u>, India's national biometric system, fell victim to a major data breach as threat actors gained access to the personal information of more than one billion Indian residents. The threat actors later offered a paid service via WhatsApp to help victims retrieve their information, including names, addresses, postal codes, photos, phone numbers, and email addresses.
- January: The Chinese smartphone manufacturer, <u>OnePlus</u>, fell victim to a credit card data breach affecting more than 40,000 customers. A malicious script was injected into its payment page code and was able to capture full credit card information, including credit card numbers, expiry dates and security codes directly from the browser window.
- **April:** Careem, the United Arab Emirates version of Uber was hacked and the private data of 14 million drivers and customers was <u>stolen</u> including names, phone numbers, email addresses and ride data.
- June: Honda Car India left <u>personal data</u> of over 50,000 users exposed on two public unsecured Amazon S3 buckets. The exposed data belonged to the users of the remote car management app Honda Connect App and included names, phone numbers, emails, passwords, Car VIN, Car Connect IDs and more.

Mid-year Data Breaches Timeline

Global Top Exploited Vulnerabilities

The top attacks list presented below is based on data collected by Check Point's Intrusion Prevention System (IPS) solution and details some of the most popular and interesting attack techniques and exploits observed by Check Point researchers in the first half of 2018.

Drupalgeddon2 and Drupalgeddon3 (CVE-2018-7600, CVE-2018-7602)

The exposure of highly critical flaws in Drupal, the Content Management System (CMS) giant, had a significant impact on the threat landscape. The vulnerabilities, affecting over a million Drupal websites, may have allowed an unauthenticated attacker to perform remote code executions on Drupal installations, taking full control over the affected website. Proofs of concept that were released put the unpatched Drupal sites under constant <u>attack</u>. These attacks ranged from various kinds of crypto-miners placed both on servers and websites, to delivering RATs and infostealer malware, conducting Tech support scams and creating massive botnets.

RTF (CVE-2017-11882, CVE-2017-0199, CVE-2018-0802)

Security flaws in Microsoft Office Rich Text Format (RTF) were widely abused by threat actors throughout the first half of 2018. These security flaws allow attackers to download and execute malicious scripts containing PowerShell commands on target machines, depending only on the end-user's decision to open malicious documents. This year we have witnessed these vulnerabilities highly used in malspam campaigns, including several lunched by <u>APT groups</u>, and within documents employed as downloaders for various malware types. Among them are the malware <u>LockyBot</u>, <u>Remcos RAT</u>, <u>KevDroid Android RAT ThreadKit exploit builder kit</u> and <u>Zyklon</u>.

"Double kill" (CVE-2018-8174)

Double Kill is a remote code execution Internet Explorer (IE) zero-day vulnerability of Windows VBScript engine, affecting the latest versions of IE and any other applications that utilize IE components. When exploited, this vulnerability allows remote attackers to embed malicious VBScript to Office documents or websites and run malicious payloads that are loaded from a remote server. It has been two years since a zero-day vulnerability was found in the browser and the discovery of this one has made many headlines in 2018, leveraged by threat actors such as the <u>APT-C-06 group</u>, and also exploited by the infamous <u>RIG Exploit Kit</u> to deliver a Monero Cryptominer.

IoT vulnerabilities (CVE-2018-10561, CVE-2018-10562)

This year security flaws were found in over one million Dasan GPON home routers, exposing them to a wide range of attacks. These vulnerabilities allow any attacker to access the router's settings by appending a certain string to any URL and gain control over the device. The vulnerabilities were widely leveraged by botnet herders to recruit their armies, among them the <u>Satori</u>, <u>Mirai</u> and <u>TheMoon</u> botnets.

Interestingly, according to Check Point global attack sensors, throughout the first half of 2018 99% of the attacks observed leveraged vulnerabilities registered in 2017 and earlier and over 40% of attacks used vulnerabilities that are at least seven years old.

Figure 24: Percentage of attacks leveraging vulnerabilities found since 2012 and earlier.

Additional Observations / Conclusions

With the fifth generation of the cyber threat landscape now firmly established, it should come as no surprise that the types of threats seen in 2017 have continued into 2018. Neither do they show any sign of slowing. If anything, they have become more entrenched and are now reaching deeper into organizations' IT infrastructure.

Whether by embedding themselves through preinstalled malware in the mobile supply chain or leveraging cloud platforms' higher computing resources to mine the valuable cryptocurrencies, threat actors are adapting today's technologies to their own financial gain. In addition, large data breaches have not abated either, bringing reputational damage as well as large financial costs to those that experience them.

As a result, it is imperative that organizations worldwide equip themselves with the highest and most advanced protection technologies in order to keep ahead of these trends and prevent themselves from being the next victim to hit the headlines.

Recommendations

What is needed is an advanced protection technology that can give you zero-day prevention from unknown and more sophisticated attacks that may bypass traditional signature-based technologies.

Check Point Sand Blast provides that technology by consisting of two main elements: **Threat Emulation and Threat Extraction.**

Threat Emulation is an extremely powerful evasion resistant sandbox technology which is proactively combined with Threat Extraction to deliver clean files to users. By combining these two elements, a proactive approach that means only clean files are allowed to enter the organization and with threat emulation that can identify zero-day and unknown malware that is attempting to enter your network, you can ensure very strong coverage for the unknown element of cyber attacks in general and crypto mining attacks in particular.

Sand Blast also includes a family of products designed to cover your entire IT infrastructure.

Sand Blast is available across all Check Point gateways to protect your mail, users browsing the web within your network and your data centers.

Sand Blast Agent on the endpoint will give you direct advanced protections on all of your endpoints and integrated protections for the browsers within the endpoint, for as we have seen, web browsing is a fundamental way of being attacked.

Sand Blast is also a core part of Cloud Guard, which covers both SaaS and IaaS so that all of your cloud assets can also be covered by this advanced technology.

Sand Blast Mobile gives you coverage for iOS and Android against all forms of known and unknown mobile attacks, including Man-in the-Middle attacks over Wi-Fi networks, malicious links sent over SMS and OS exploits.

Sand Blast also comes with an API which means you can integrate the capabilities of Sand Blast with any business process or business logic that you have that is not strictly covered by the other products in the Sand Blast family.

Appendix – Malware Family Descriptions

Andromeda	Andromeda is a modular bot for malicious activity, and was first spotted in
	2011. It is used mainly as a backdoor to deliver additional malware on
	infected hosts, but can be modified to create different types of botnets.
AndroRAT	AndroRAT is an open-source tool that first emerged in November 2012,
	targeting Android devices. AndroRAT allows a remote attacker to take
	control over the victim's machine, make phone calls and send SMS
	messages of infected devices, access victim's GPS coordinates, and use the
	microphone and camera.

Authedmine	Authedmine is a version of the infamous JavaScript miner CoinHive.
	Similarly to CoinHive, Authedmine is a web-based crypto miner used to
	perform online mining of Monero cryptocurrency when a user visits a web
	page without the user's knowledge or approval the profits with the user.
	However, unlike CoinHive, Authedmine is designed to require the website
	user's explicit consent before running the mining script.
Bancos	Bancos steals financial information, using keylogging to record the victim's
	credentials as they are entered on a targeted bank webpage. Bancos can
	also supplement or replace a legitimate bank login page with a fake
	webpage.
Cerber	Cerber, also known as Zerber, which was first introduced in February 2016,
	is an offline Ransomware, meaning that it does not need to communicate
	with its C2 server before encrypting files on an infected machine.
Coinhive	Crypto Miner designed to perform online mining of Monero
	cryptocurrency when a user visits a web page without the user's approval.
	The implanted JS uses great computational resources of the end users
	machines to mine coins, thus impacting its performance.
Cridex	Cridex is a worm for Windows platform. It attempts to steal victim's
	credentials, such as credit card information. It can download and execute
	other malicious files on to the infected system. It may spread itself via
	removable drives and network shares.
Cryptolocker	Cryptolocker is a Ransomware, first detected in 2013, which targets
	Windows platform. It runs in the background and encrypts various files and
	documents found on compromised hosts.
Cryptoloot	A JavaScript Cryptominer, designed to perform online mining of Monero
	cryptocurrency when a user visits a web page without the user's approval.
	The implanted JS uses great computational resources of the end users
	machines to mine coins, thus impacting its performance. It is a competitor
	of Coinhive.
Cryptopool	Web-based Crypto miner designed to perform online mining of Monero
	cryptocurrency when a user visits a web page without the user's approval.
	1

	The implanted laveScript uses great computational resources of the and
	The implanted JavaScript uses great computational resources of the end
	users' machines to mine coins, thus impacting the performance of the
	system.
Cryptowall	Cryptowall is a leading Ransomware Trojan which encrypts files on an
	infected machine and then asks users to pay for them to be decrypted. It
	spreads through malvertising and phishing campaigns. Cryptowall first
	appeared in 2014.
Dorkbot	IRC-based Worm designed to allow remote code execution by its operator,
	as well as the download of additional malware to the infected system, with
	the primary motivation being to steal sensitive information and launch
	denial-of-service attacks.
Dorvku	Dorvku is Trojan that targets the Windows platform. The malware collects
	system information and sends it to a remote server. It also collects
	sensitive information from targeted web browsers.
Fireball	Fireball is an adware vastly distributed by the Chinese digital marketing
	company Rafotech. It acts as a browser-hijacker which changes the default
	search engine and installs tracking pixels, but can be turned into a full-
	functioning malware downloader.
Gamarue	Gamarue is a modular bot with a loader, which downloads additional
	modules from its C&C server. The loader has both anti-VM and anti-debug
	features. It injects into trusted processes to hide itself and then deletes the
	original bot.
GandCrab	GandCrab is a Ransomware which targets mainly Scandinavia and the
	English-speaking countries. GandCrab is distributed via the Rig and
	GrandSoft exploit kits, as well as email spam. The Ransomware is operated
	in an affiliates program, with those joining the program paying 30%-40% of
	the ransom revenues to GandCrab author. In return affiliates get a full-
	featured web panel and technical support.
Globeimposter	GlobeImposter is a Ransomware disguised as a variant of the Globe
	Ransomware. It was discovered in May 2017, and is distributed by spam
	campaigns, malvertising and exploit-kits.
L	1

GraftorGraftor is an adware and browser-hijacker that has Trojan-like capabilities. It can be used as an attack vector for other malicious software. It is also known for hiding executables and DLLs in PNG files to avoid detectionHackerDefenderHackerDefender is a rootkit for Windows 2000 and Windows XP, and may also work on later Windows NT based systems. The rootkit modifies several Windows and native API functions to remain undetected by security softwares.HiddadAndroid malware which repackages legitimate apps, and then release them to a third-party store. Its main function is displaying ads, however it is also able to gain access to key security details built into the OSHiddenMinerA strain of Android Cryptominer that has been spotted in April 2018. The HiddenMiner is delivered through a fake Google Play update app, exhausting the devices resources in mining Monero.JsecoinWeb-based Crypto miner designed to perform online mining of Monero cryptocurrency when a user visits a web page without the user's approval. The implanted JavaScript uses great computational resources of the end users' machines to mine coins, thus impacting the performance of the system.KrakenKraken is a Ransomware Trojan that targets the Windows platform. The malware collects system information and sends it to a remote attacker via Discord chat service. The malware encrypts files with the specific extensions on the infected system. It downloads and executes the decryptor on the infected system to demand the infected user to pay a ransom in order to get the files decrypted. It also can kill processes.LockyLocky is a Ransomware Trojan which targets Android smartphones and turns into a Ransomware, upon an attempt of the victim to remove its admin		
Income for hiding executables and DLLs in PNG files to avoid detectionHackerDefenderHackerDefender is a rootkit for Windows 2000 and Windows XP, and may also work on later Windows NT based systems. screens on top of popular banking applications. The banker targets mobile		screens on top of popular banking applications. The banker targets mobile

	banking apps by their design, but also other popular apps such as
	WhatsApp, Outlook and Skype.
Lotoor	Lotoor is a hack tool that exploits vulnerabilities on Android operating
	system in order to gain root privileges on compromised mobile devices.
Necurs	Necurs is a one of the largest spam botnet currently active in the wild, and
	it is estimated that on 2016 it consisted of some 6 million bots. The botnet
	is used to distribute many malware variants, mostly banking Trojans and
	Ransomware.
Nivdort	Nivdort is a Trojan family which targets the Windows platform.
	It gathers passwords and system information or settings such as the
	Windows version, IP address, software configuration and approximate
	location.
Nymaim	Nymaim is a malware dropper and downloader, first observed in 2013.
	Originally, Nymaim dropped Ransomware, after being distributed by the
	Black Hole Exploit Kit. Later, Nymain was responsible for the distribution of
	additional types of malware such as Vawtrak, Miuref, Pony, and Ursnif. The
	malware's distribution dropped at 2014, and increased again in 2015.
Panda	Panda is a Zeus variant that was first observed in the wild at the beginning
	of 2016, and is distributed via Exploit Kits. Since its initial appearance,
	Panda has targeted financial services in Europe and North America. Before
	the Olympic Games of 2016, it also ran a special campaign against Brazilian
	banks.
Parite	Parite is a polymorphic virus which infects executable files (EXE and SCR)
	on the infected host and on network drive. It drops a malicious DLL file into
	the Windows temporary directory which is injected into the explorer.exe
	process.
Ponmocup	Ponmocup is a Botnet which has been active as of 2006 and has reached its
	peak in 2011, with approximately 2.4 million controlled machines. Its
	infrastructure is complex and includes dedicated servers for various tasks.
Proslikefan	Proslikefan is a Worm that targets Windows systems supporting JavaScript.
	This malware attempts to spread through network shares, removable

	drives, and peer-to-peer programs. It attempts to send system information
	to a remote server.
Qbot	Qbot is a backdoor belonging to the Qakbot family. It is capable of
	dropping and downloading other malware. It also establishes a connection
	with a remote HTTP server without user consent and steals sensitive
	information.
Ramnit	Ramnit is a banking Trojan which incorporates lateral movement
	capabilities. Ramnit steals web session information, giving the worm
	operators the ability to steal account credentials for all services used by
	the victim, including bank accounts, corporate and social networks
	accounts.
Rig Exploit Kit	Rig EK was first introduced in April 2014. It has since received several large
	updates and continues to be active to this day. Rig serves many threat
	actors while distributing their malware among the victims it succeeded to
	exploit.
Roaming Mantis	Roaming Mantis is an Android banking Trojan first emerged on March
	2018, capable of stealing users' sensitive information, login credentials and
	the secret code for two-factor authentication. Roaming Mantis being
	distribute using DNS hijacking attacks, disguised as Chrome browser or
	Facebook apps. An evolved version of Roaming Mantis is also targeting iOS
	devices with phishing attacks, and desktops and laptops with the CoinHive
	cryptomining script.
RottenSys	RottenSys is a widespread Android oriented Trojan that has targeted nearly
	5 million Android devices. RottenSys came preinstalled on the devices
	disguised as a legitimate 'System Wi-Fi service' app. RottenSys malware is
	originally used to aggressively display ads on users' devices, but also have
	extensive capabilities including silently installing additional apps and UI
	automation.
Roughted	Large scale Malvertising campaign used to serve various malicious websites
	and payloads such as scams, adware, and Ransomware. It can be used to
	attack any type of platform and operating system, and utilizes ad-blocker

	bypassing and fingerprinting.
RubyMiner	Rubyminer is a Monero miner targeting both Windows and Linux servers
	trying to find vulnerable versions (such as PHP, Microsoft IIS, and Ruby on
	Rails) in order to mobilize them to his mining pool, and to install the open
	source Monero miner named XMRig.
Sality	Sality is a virus which spreads itself by infecting .exe and .scr files as well as
	via removable drives and network shares. Systems infected with Sality can
	communicate over a peer-to-peer (P2P) network for spamming purposes.
Smokeloader	SmokeLoader is a Trojan that enables an attacker to remotely control an
	infected computer and perform a range of malicious activities including
	downloading and installing other malware based on the geo-location of the
	victim, and stealing passwords.
TheTruthSpy	An Android spyware, first emerged in May 2017. The Truth Spy is capable of
	monitoring of WhatsApp messages, Facebook chats, and internet browsing
	history.
Tinba	Tinba is a banking Trojan which targets mainly European banking
	customers and uses the BlackHole exploit kit. Tinba steals the victim's
	credentials using web-injects, which are activated as the user tries to
	connect his account.
Triada	Modular Backdoor for Android which grants super-user privileges to
	download a malware. Triada has also been seen spoofing URLs loaded in
	the browser.
TrickBot	Trickbot is a Dyre variant that emerged in October 2016. Since its first
	appearance, it has been targeting banks mostly in Australia and the U.K,
	and lately it has started appearing also in India, Singapore and Malesia.
WannaCry	Ransomware which was spread in a large scale attack on May 2017,
	utilizing a Windows SMB exploit called EternalBlue in order to propagate
	within and between networks.
XMRig	XMRig is open-source CPU mining software used for the mining process of
	the Monero cryptocurrency, and first seen in-the-wild on May 2017.
Zeus	Zeus is a widely distributed Windows Trojan which is mostly used to steal

banking information. When a machine is compromised, the malware sends
information such as the account credentials to the attackers using a chain
of C&C servers.
